

A word cloud centered on the word "creative". The word "creative" is the largest and most prominent, rendered in a bright green color. Surrounding it are numerous other words in various sizes and colors, including white, yellow, orange, and blue. The words are arranged in a roughly circular pattern, with some overlapping. The overall theme is creativity, innovation, and imagination.

## **DEFINING CREATIVITY**

**Don't We Also Need to Define What's *Not* Creative?**

# THE IMPORTANCE OF DEFINING OUR TERMS: WHAT DOES “CREATIVITY” ACTUALLY MEAN?

- Presumably creativity must involve the “creative idea”
  - A creative process or (procedure) generates creative ideas
  - A creative person uses a creative process (or procedure) to generate those ideas
  - A creative product provides a vehicle for communicating those ideas to others
- But without a rigorous definition of the creative idea, scientific research on the process, person, and product becomes impossible:
  - You can't measure something when you have absolutely no conception of what you're actually measuring!
- Unfortunately, creativity researchers have not yet reached a consensus on what creativity actually means (e.g., Plucker, Beghetto & Dow, 2004, p. 89).
- Even worse, the most common definitions are a complete mess!

# FOUR QUESTIONS THAT *MUST* BE ADDRESSED IN ANY DEFINITION OF CREATIVITY

- How many criteria?
  - Two or three?
- What are the criteria?
  - Originality, novelty, or uniqueness?
  - Utility, usefulness, adaptiveness, appropriateness, relevance, effectiveness, meaningfulness, or value?
  - Surprise, nonobviousness, or heuristic rather than algorithmic task?
- How are the criteria assessments scaled?
  - Qualitative? Quantitative? If latter, how scaled?
- How are the criteria assessments integrated?
  - Additive? Multiplicative?
- Who assesses the criteria?
  - Personal assessment? Consensual assessment?

# ILLUSTRATIONS OF PRIOR DEFINITIONS

## ○ Two-criteria definitions

- The “standard definition,” namely, “Creativity requires both **originality and effectiveness**” (Runco & Jaeger, 2012, p. 92)
- Bruner’s (1962) “effective surprise” (p. 18), or **surprising and effective**
- Weisberg’s (2015) “intentional novelty,” or **novel and intentional**
- Cf. Kaufman & Sternberg’s (2010) “a creative response is novel, good, and relevant” (p. xiii), which *splits* the second criterion into two criteria

# ILLUSTRATIONS OF PRIOR DEFINITIONS

## ○ Three-criteria definitions

- Boden's (2004) **novel, valuable, and surprising**
- US Patent Office's **new, useful, and nonobvious**
- Cf. Amabile's (1996) "a product or response will be judged as creative to the extent that (a) it is both a novel and appropriate, useful, correct, or valuable response to the task at hand, and (b) the task is heuristic rather than algorithmic" (p. 35), which *lumps* the first two criteria into one criterion and then adds the third, which closely parallels surprising or nonobvious

# ILLUSTRATIONS OF PRIOR DEFINITIONS

- Problems with all of the foregoing definitions: None are explicit about
  - whether the criteria are quantitative or qualitative
  - whether the assessments of the criteria are to be integrated using either additive or multiplicative integration
  - whether the criteria assessments are personal or consensual
- Hence, the necessity for a definition that explicitly deals with these additional issues as well as specifies the nature and number of the criteria

## PROLOGUE TO THE PROPOSED DEFINITION

- The proposed definition will be founded on pure logic to render the most rigorous definition possible
- In particular, the definition will *not* depend on either ...
  - Data (cf. Diedrich, Benedek, Jauk, & Neubauer, 2015, who concluded that novelty was more important than usefulness according to undergraduate participants) or the
  - Dictionary (cf. Weisberg, 2015, who argued on this basis that value is useless)
- Instead, the definition will depend solely on the parameters that are absolutely essential to fully describe any person's response to a given situation, such as a solution to a particular problem (whether a thought or a behavior)
- Those parameters must be defined first, then creativity will follow

# THE THREE PARAMETERS DELINEATING A PERSON'S RESPONSE TO A GIVEN SITUATION:

- The response's *initial probability*  $p$ , where  $0 \leq p \leq 1$ 
  - Also may be called the “initial response strength”
  - Can be used to define the response's *originality*, which equals  $(1 - p)$
- The response's *final utility*  $u$ , where  $0 \leq u \leq 1$ 
  - If  $u$  is dichotomous, then  $u = 0$  if useless and  $u = 1$  if useful
  - If  $u$  is continuous, then  $u$  indicates (a) the *probability* of acceptance, (b) the *proportion* of criteria satisfied, or (c) the *benefit-cost ratio* scaled to a 0-1 metric (depending on the task demands), where  $u < 1$  suggests *satisficing*
  - Here “final” means the utility after the response is generated and tested
- The utility's *prior knowledge value*  $v$ , where  $0 \leq v \leq 1$  once more
  - Can be used to define response *surprise*, which equals  $(1 - v)$
  - i.e.,  $(1 - v) = 1$  = “surprising,”  $(1 - v) = 0$  = “obvious,”  $(1 - v) \approx .5$  = “hunch”

# TWO CRITICAL PARAMETER CHARACTERISTICS

- First, all three parameters can assume independent values
  - To illustrate,
    - if  $u = 0$ , then still  $0 \leq v \leq 1$  (response *uselessness* may or may not be known in advance)
    - if  $u = 1$ , then still  $0 \leq v \leq 1$  (response *usefulness* may or may not be known in advance)
  - However, given the three parameters together, then two rational constraints result
    - If  $v \rightarrow 1$  and  $u \rightarrow 0$ , then  $p \rightarrow 0$  (i.e., known useless responses get low probabilities)
    - If  $v \rightarrow 1$  and  $u \rightarrow 1$ , then  $p \rightarrow 1$  (i.e., known useful responses get high probabilities)
    - where “ $\rightarrow$ ” indicates “approaches” or “nears”

# TWO CRITICAL PARAMETER CHARACTERISTICS

- Second, all three parameters are *personal* rather than *consensual*
  - In particular, the utility  $u$  does *not* require the direct endorsement by others, a consensual process that involves so many interpersonal, social, cultural, economic, political, ideological, and historical factors that *consensual* creativity would cease to be *psychological* (cf. Csikszentmihályi, 2014; Weisberg, 2015)
    - E.g., the so-called “neglected” or “rediscovered” genius (such as Emily Dickinson)
  - Even so, to the extent that persons have acquired sufficient domain-specific expertise in a high-consensus field the correspondence between personal and consensual appraisals will be fairly high (Simonton, 2013, 2015)
    - E.g., peer review in the natural sciences (such as Albert Einstein)

# RESPONSE PERSONAL CREATIVITY DEFINED

- Given the foregoing three parameters, a response's *personal* (or “little *c*”) *creativity* is defined as  $c = (1 - p)u(1 - v)$ , where  $0 \leq c \leq 1$
- In words, personal creativity is a multiplicative function (or “joint product”) of originality, utility, and surprise
- Hence, personal creativity is absent if  $c = 0$ , but maximal if  $c = 1$ , creativity most often assuming values in more middling ranges
  - E.g., if  $p = .2$ ,  $u = .8$ , and  $v = .5$ , then  $c = (1 - .2)(.8)(1 - .5) = .32$  (1/3<sup>rd</sup> up the scale)
- Moreover, because the three criteria undergo a multiplicative rather than additive integration, each factor retains “veto power” over the others (i.e., in logical terms, each factor is necessary but not sufficient):
  - commonplace, useless, and/or obvious responses cannot be creative, period
  - additive integration (e.g., just averaging the three factors) lacks this property
    - E.g., a hot air balloon made out of steal reinforced concrete (additive  $c = 1/3^{\text{rd}}$  up the scale)

# THE DEFINITION'S CRITICAL IMPLICATIONS: EACH PARAMETER TAKEN SEPARATELY

- Because  $c \rightarrow 1$  as  $p \rightarrow 0$ , then whenever  $u > 0$  and  $v < 1$ , then creativity maximizes when  $p = 0$  (i.e., the response is not immediately available)
  - Thus, maximally creative responses require an incubation period
  - However, the length of the incubation period is unrelated to creativity
- Because  $c \rightarrow 1$  as  $v \rightarrow 0$ , then whenever  $u \rightarrow 1$  and  $p \rightarrow 0$ , then maximal personal creativity requires the implementation of BSVR processes or procedures (i.e., blind variation and selective retention; Campbell, 1960):
  - After all,  $v \rightarrow 0$  indicates the extent to which the person is *blind* to  $u$ , thus requiring a generation and test or trial and error episode to determine  $u$
  - Any process or procedure that supports implicit or explicit BSVR is potentially creative
  - In other words, there's no such thing as *the* creative process or procedure, only alternative strategies for producing potentially creative ideas

# THE DEFINITION'S CRITICAL IMPLICATIONS: THE THREE PARAMETERS TAKEN JOINTLY

- ▶ First, the distribution of  $c$  must be highly skewed, low creativity responses far more frequent than high creativity responses
  - ▶ The distribution best described by an inverse-power function
  - ▶ E.g., a Monte Carlo simulation (Simonton, 2012)

# THE DEFINITION'S CRITICAL IMPLICATIONS: THE THREE PARAMETERS TAKEN JOINTLY

- Second, although the high creative responses form a homogeneous group, all being original, useful, and surprising, the low  $c$  responses form an extremely heterogeneous group, with *seven* alternative ways of being uncreative
  - Cf. Leo Tolstoy's opening to his novel *Anna Karenina*: "All happy families are alike; each unhappy family is unhappy in its own way."
  - Hence, let us examine these seven uncreative responses, starting with those with a high initial probability and then turning to those with a low initial probability

# THE SEVEN UNCREATIVE RESPONSES: FOUR WITH *HIGH* INITIAL PROBABILITY

- 1. Habitual (“reproductive” or “routine”) responses:  $p \rightarrow 1$ ,  $u \rightarrow 1$ , and  $v \rightarrow 1$ 
  - In words, the response has a high probability because it has a high utility and that high utility is already known in advance (for rational creatures, as  $uv \rightarrow 1$ ,  $p \rightarrow 1$ )
  - If  $p = u = v = 1$ , we can even speak of *automaticity*
  - Such responses represent the established *expertise* that maintains adaptive behavior at both home and work

## THE SEVEN UNCREATIVE RESPONSES: FOUR WITH *HIGH* INITIAL PROBABILITY

- 2. Fortuitous responses:  $p \rightarrow 1$ ,  $u \rightarrow 1$ , but  $v \rightarrow 0$ 
  - In words, the response has a high probability and a high utility, but that the prior knowledge of that utility is near nil, rendering it a “lucky guess”
  - E.g., the traveler coming to a fork in the road

# THE SEVEN UNCREATIVE RESPONSES: FOUR WITH *HIGH* INITIAL PROBABILITY

- 3. Irrational perseveration:  $p \rightarrow 1$ ,  $u \rightarrow 0$ , but  $v \rightarrow 1$ 
  - A “habitual” response remains so despite knowing full well that it is maladaptive
  - “The definition of insanity is doing the same thing over and over and expecting it to come out different.”
  - E.g., continuing to live with an abusive partner whose promises to reform repeatedly fail

# THE SEVEN UNCREATIVE RESPONSES: FOUR WITH *HIGH* INITIAL PROBABILITY

- 4. Problem finding:  $p \rightarrow 1$  but  $u \rightarrow 0$  and  $v \rightarrow 0$ 
  - A response that has a high probability but low utility is emitted because that low utility is unknown in advance
  - The person has unexpectedly learned the limits of their expertise
  - And because  $(1 - v) \rightarrow 1$ , the result is highly surprising!
  - Problem finding constitutes a major stimulus for creativity (e.g., anomalies in paradigmatic sciences)

# THE SEVEN UNCREATIVE RESPONSES: THREE WITH *LOW* INITIAL PROBABILITY

- 1. Rational suppression:  $p \rightarrow 0$  because  $u \rightarrow 0$  and  $v \rightarrow 1$ 
  - E.g., the extinction of a maladaptive response through punishment or non-reinforcement
  - As *pre-selection*, plays a key role in BVSR creativity (Simonton, 2011)
    - The creator need not generate and test what is already known to be useless!
      - E.g., a theoretical physicist pre-selects out of consideration any idea that would violate a fundamental law of nature, such as the three laws of thermodynamics
    - Hence, in this sense BVSR can be “sighted” even while testing “blind” variations (cf. Sternberg, 1998)

# THE SEVEN UNCREATIVE RESPONSES: THREE WITH *LOW* INITIAL PROBABILITY

- 2. Irrational suppression:  $p \rightarrow 0$  even though  $u \rightarrow 1$  and  $v \rightarrow 1$ 
  - Even though a person knows what's the best thing to do, he or she does not do it
  - E.g., adaptive behaviors suppressed by a phobia or other excessive anxiety
  - N.B.: This uncreative response pinpoints a problem with the standard definition
    - If the third criterion is omitted, the *standard* definition becomes  $c = (1 - p)u$
    - Yet how is it even possible for  $p \rightarrow 0$  if  $u \rightarrow 1$ ?
    - The obvious answer is that  $v \rightarrow 0$
    - If otherwise, then we must get irrational suppression rather than creativity
    - Ergo, the standard definition is untenable, period

# THE SEVEN UNCREATIVE RESPONSES: THREE WITH *LOW* INITIAL PROBABILITY

- 3. Mind wandering or behavioral exploration:  $p \rightarrow 0$ ,  $u \rightarrow 0$ , and  $v \rightarrow 0$ 
  - Two major examples
    - Mind wandering, such as fantasy and daydreaming (cf. the “default network”)
    - Behavioral exploration, such as play, tinkering, and “fool’s experiments” (Darwin, 1892)
      - But also systematic and heuristic searches (e.g., searching for the needle in the haystack, such as Edison’s “drag hunts”; Simonton, 2015)
  - Indeed, only this type of response has any chance whatsoever of inadvertently generating a creative response
    - all others are defined by  $p \rightarrow 1$  or  $v \rightarrow 1$  or both
    - although creativity requires  $u \rightarrow 1$ , that possibility is not precluded because  $v \rightarrow 0$
  - Hence, these parameter values define what takes place in the *incubation* period that comes between the *preparation* and *illumination* periods

# ILLUSTRATIONS: MAIER'S (1931) "TWO-STRINGS" PROBLEM

# ILLUSTRATIONS: MAIER'S (1931) "TWO-STRINGS" PROBLEM

- Problem finding – yes!
- Rational suppression – possibly!
- Irrational perseveration – sort of ...
- Habitual – yes, and more than one!
- Creative – yes!
- Fortuitous – not really ...
- Irrational suppression – unknown
- Mind wandering or behavioral exploration – presumably yes!

# CONCLUSIONS

- The standard definition of creativity (or any other two-criterion definition) is absolutely incapable of representing the diversity of uncreative responses
  - In particular, if the third “surprise” criterion ( $1 - v$ ) is omitted, the number of uncreative responses must shrink from 7 to just 3, fewer than half as many
  - That reduction necessarily conflates (a) creativity with irrational suppression, (b) habitual with fortuitous responses, (c) problem finding with irrational perseveration, and (d) rational suppression with mind wandering or behavioral exploration – equivalences that make no logical or psychological sense
- Because creativity is tridimensional, it cannot possibly form one end of a bipolar dimension with uncreative anchoring the other end – a three-dimensional space is required to represent all response possibilities
- BVSR processes and procedures are then shown to be absolutely essential to creativity, with the corresponding participation of problem finding, rational suppression, and mind wandering or behavioral exploration
